INTRODUCTION

Urbanization, driven by human interaction with the environment, alters land use.

Likewise, urbanization leads to Urban Heat Islands due to climate and land use changes.

UHI intensity correlates with urbanization

Impact of urbanization on urban LST variance can be assessed using geospatial tools

In this study, geospatial tools are employed to analyze the impact of urbanization on urban land surface temperature variance in the study area.

INTRODUCTION cont.

The study area Soba LGA is in Kaduna State, Nigeria.

It is between $10^{\circ} 20' 06''$ to $10^{\circ} 59' 60''$ N & $8^{\circ} 03' 32''$ to $8^{\circ} 30' 15''$ E

It covers an area of 2,234 km²

MATERIALS AND METHODS

- Land cover classification
- Derivation of NDVI and NDBI
- Land Surface Temperature (LST) retrieval
- Urban Heat Island Estimation
- Growth rate

Table 3

Co de	Land use / Landover	Description
1	Agricultural land	Lands used for farming (Plantation, Cropland orchard)
2	Built-up land	Lands used for residential, industrial, commercial, etc.
3	Grassland / Forest cover	Lands covered with natural vegetation (plant species)
4	Bare surfaces	Lands devoid of vegetation exposed soil
5	Water bodies	Areas with lakes, rivers, and streams.

and Sustainable
Resource Management
for All

RESULTS AND ANALYSES

Effect of Urbanization on Vegetation

- NDVI pixels values range from -1 to +1. The higher NDVI levels suggest vegetation that is both more abundant and healthier.
- In 2001, the NDVI value ranged from -0.95 to 0.84, whereas in 2011, the value ranged from -0.2 to 0.42. The 2021 ranged from -0.09 to 0.56, lower than in 2001.
- The lower NDVI values are associated with more developed places, while higher NDVI values are associated with more naturally occurring surfaces, suggesting that urbanization does have an impact on the amount of vegetation.

RESULTS AND ANALYSES

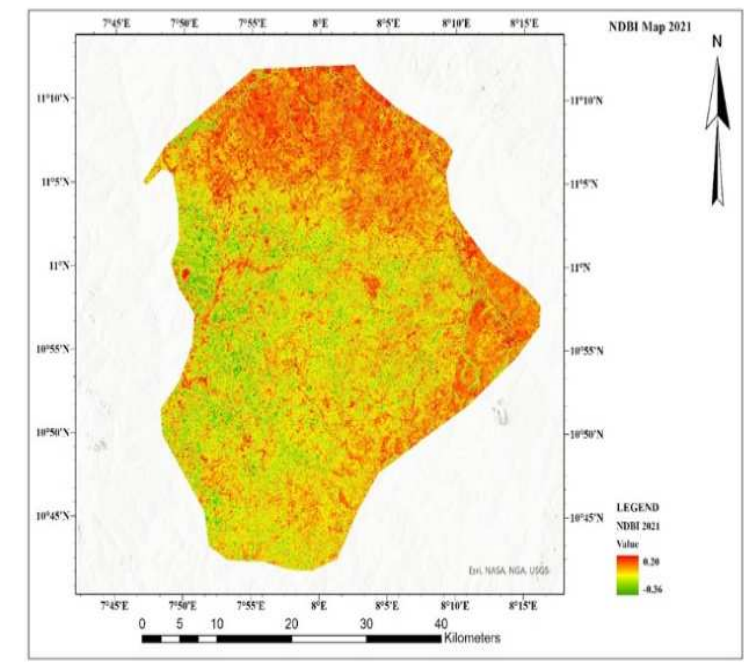

Effect of Urbanization on Vegetation

- The NDBI was used to identify built-up regions.
- The positive NDBI values are linked to more developed settlements, and negative NDBI values are linked to less developed natural surfaces.
- The NDBI values generally indicate that built-up areas have grown, whereas other land uses and land cover, particularly forest cover, have also increased and occasionally water decreased.

Resource Management
for All

RESULTS AND ANALYSES

Results show linear regression correlations between the elements and the relationship between LST and NDVI.

There is a weak correlation between LST and NDVI. This suggests that the amount of LST that may be obtained at a specific place is influenced by the presence of vegetation.

And it can be said that when vegetation is present, the temperature is lower than in an area that is built up.

for All

CONCLUSION

There were significant changes in land cover, and the surface temperature has been noticeably rising due to increased development and a dearth of water bodies.

There was a weak link between LST and NVDI, however, NDBI and LST had a positive association since the correlation showed that LST rose as the built-up area grew.

Improving vegetation cover in the area will lessen the impact of UHI

It is recommended that the State Government should regularly monitor urban growth; and prioritize the plantation of trees within the community centers.
